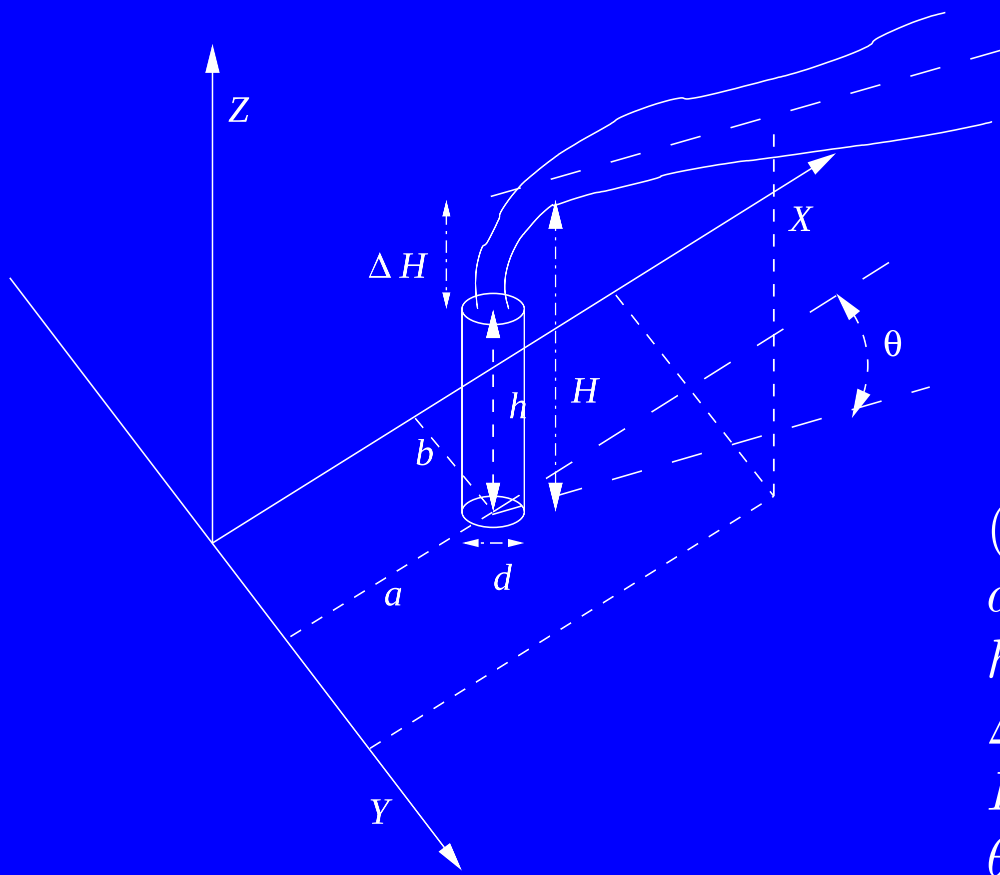
Semi-infinite programming

$$
\begin{aligned}
\min_{u \in R^n} \ & f(u) \\
s.t. \ \ & g_i(u,v) \le 0, \ i = 1, \ldots, m \\
& u_{lb} \le u \le u_{ub} \\
& \forall v \in \mathcal{R} \subset R^p,
\end{aligned}
$$

where $f(u)$ is the objective function, $g_i(u,v)$, $i = 1, \ldots, m$ are the infinite constraint functions and u_{lb}, u_{ub} are the lower and upper bounds on u.

Coordinate system



(a, b)	stack position
d	stack internal diameter
h	stack height
ΔH	plume rise
$H = h + \Delta H$	effective stack height
θ	mean wind direction

Dispersion model

Assuming that the plume has a Gaussian distribution, the concentration, of gas or aerosol (particles with diameter less than 20 microns) at position x, y and z of a continuous source with effective stack height $\mathcal{H}$, is given by

$$\mathcal{C}(x,y,z,\mathcal{H}) = \frac{\mathcal{Q}}{2\pi\sigma_y\sigma_z\mathcal{U}} e^{-\frac{1}{2}\left(\frac{\mathcal{Y}}{\sigma_y}\right)^2} \left(e^{-\frac{1}{2}\left(\frac{z-\mathcal{H}}{\sigma_z}\right)^2} + e^{-\frac{1}{2}\left(\frac{z+\mathcal{H}}{\sigma_z}\right)^2} \right)$$

where $\mathcal{Q}$ (gs^{-1}) is the pollution uniform emission rate, $\mathcal{U}$ (ms^{-1}) is the mean wind speed affecting the plume, σ_y (m) and σ_z (m) are the standard deviations in the horizontal and vertical planes, respectively.

Change of coordinates

The source change of coordinates to position (a, b), in the wind direction.

$\mathcal{Y}$ is given by

$$\mathcal{Y} = (x - a)\sin(\theta) + (y - b)\cos(\theta),$$

where θ (rad) is the wind direction $(0 \leq \theta \leq 2\pi)$.

σ_y and σ_z depend on $\mathcal{X}$ given by

$$\mathcal{X} = (x - a)\cos(\theta) - (y - b)\sin(\theta).$$

Plume rise

The effective emission height is the sum of the stack height, h (m), with the plume rise, $\Delta\mathcal{H}$ (m). The considered elevation is given by the Holland equation

$$\Delta\mathcal{H} = \frac{V_o d}{\mathcal{U}} \left(1.5 + 2.68 \frac{T_o - T_e}{T_o} d \right),$$

where d (m) is the internal stack diameter, V_o (ms^{-1}) is the gas out velocity, T_o (K) is the gas temperature and T_e (K) is the environment temperature.

Formulations

- Assuming n pollution sources distributed in a region;

Formulations

- Assuming n pollution sources distributed in a region;
- $\mathcal{C}_i$ is the source i contribution for the total concentration;

Formulations

- Assuming n pollution sources distributed in a region;
- $\mathcal{C}_i$ is the source i contribution for the total concentration;
- Gas chemical inert.

Formulations

- Assuming n pollution sources distributed in a region;
- $\mathcal{C}_i$ is the source i contribution for the total concentration;
- Gas chemical inert.

We can derive three formulations:

- Minimize the stack height;
- Maximum pollution computation and sampling stations planning;
- Air pollution abatement.

Minimum stack height

Minimizing the stack height $u = (h_1, \ldots, h_n)$, while the pollution ground pollution level is kept below a given threshold $\mathcal{C}_0$, in a given region $\mathcal{R}$, can be formulated as a SIP problem

$$\min_{u \in R^n} \sum_{i=1}^{n} c_i h_i$$

$$s.t. \;\; g(u, v \equiv (x, y)) \equiv \sum_{i=1}^{n} \mathcal{C}_i(x, y, 0, \mathcal{H}_i) \leq \mathcal{C}_0$$

$$\forall v \in \mathcal{R} \subset R^2,$$

where c_i, $i = 1, \ldots, n$, are the construction costs.

Note: more complex objective function can be considered.

Maximum pollution and sampling stations planning

The maximum pollution concentration (l^*) in a given region can be obtained by solving the following SIP problem

$$\min_{l \in R} \; l$$

$$s.t. \;\; g(z, v \equiv (x,y)) \equiv \sum_{i=1}^{n} \mathcal{C}_i(x, y, 0, \mathcal{H}_i) \leq l$$

$$\forall v \in \mathcal{R} \subset R^2.$$

The active points $v^* \in \mathcal{R}$ where $g(z^*, v^*) = l^*$ are the global optima and indicate where the sampling (control) stations should be placed.

Air pollution abatement

Minimizing the pollution abatement (minimizing clean costs, maximizing the revenue, minimizing the economical impact) while the air pollution concentration is kept below a given threshold can be posed as a SIP problem

$$\min_{u \in R^n} \sum_{i=1}^{n} p_i r_i$$

$$s.t. \;\; g(u, v \equiv (x,y)) \equiv \sum_{i=1}^{n} (1 - r_i) \mathcal{C}_i(x, y, 0, \mathcal{H}_i) \leq \mathcal{C}_0$$

$$\forall v \in \mathcal{R} \subset R^2,$$

where $u = (r_1, \ldots, r_n)$ is the pollution reduction and p_i, $i = 1, \ldots, n$, is the source i cost (cleaning or not producing).

Example - Minimum stack height

Consider a region with 10 stacks. The environment temperature (T_e) is $283K$ and the emission gas temperature (T_o) is $413K$. The wind velocity $(\mathcal{U})$ is $5.64ms^{-1}$ in the $3.996rad$ direction (θ).

The stack height in the table were used as initial guess and a squared region of 40km was considered $(\mathcal{R} = [-20000, 20000] \times [-20000, 20000])$.

Data for the 10 stacks

The stacks data is

Source	a_i (m)	b_i (m)	h_i (m)	d_i (m)	$\mathcal{Q}_i$ (gs^{-1})	$(V_o)_i$ (ms^{-1})
1	-3000	-2500	183	8.0	2882.6	19.245
2	-2600	-300	183	8.0	2882.6	19.245
3	-1100	-1700	160	7.6	2391.3	17.690
4	1000	-2500	160	7.6	2391.3	17.690
5	1000	2200	152.4	6.3	2173.9	23.404
6	2700	1000	152.4	6.3	2173.9	23.404
7	3000	-1600	121.9	4.3	1173.9	27.128
8	-2000	2500	121.9	4.3	1173.9	27.128
9	0	0	91.4	5.0	1304.3	22.293
10	1500	-1600	91.4	5.0	1304.3	22.293

Numerical results

Two threshold values were tested. $\mathcal{C}_0 = 7.7114 \times 10^{-4} gm^{-3}$ without a lower bound on the stack height, $\mathcal{C}_0 = 7.7114 \times 10^{-4} gm^{-3}$ with a stack lower bound height of $10m$[1] and $\mathcal{C}_0$[2] $= 1.25 \times 10^{-4} gm^{-3}$.

The stack height can only be inferior to $10m$ if some legal[3] requirements are met. One way to prove that the requirements are met is by simulation, using a proper model, of the air pollution dispersion.

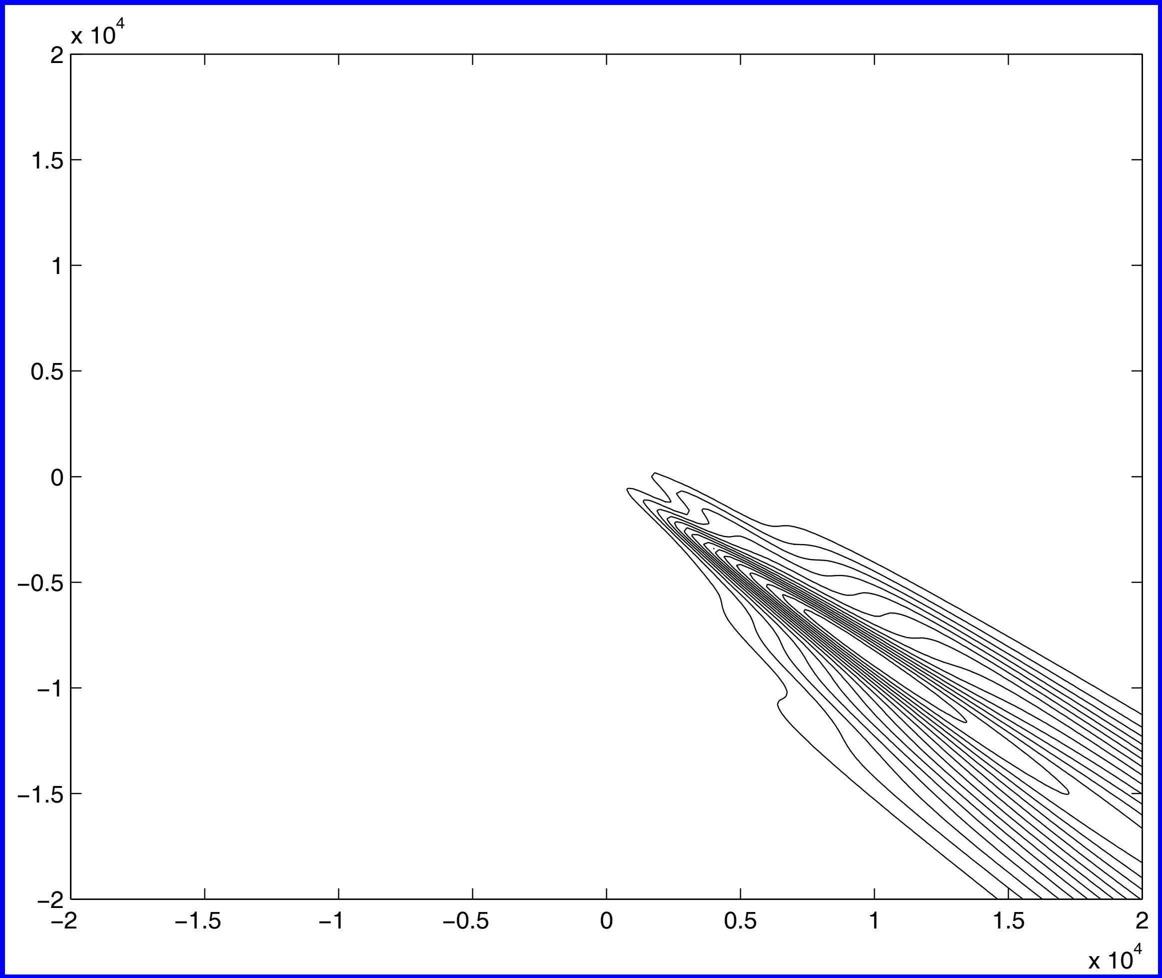
Constraint contour



Example - Maximum pollution level and sampling stations planning

Computing the maximum pollution level (l^*) by fixing the stack height h_i.

The region considered was $\mathcal{R} = [0, 24140] \times [0, 24140]$ (square of about 15 miles).

Environment temperature of $284K$, and wind velocity of $5ms^{-1}$ in direction $3.927rad$ (225^o).

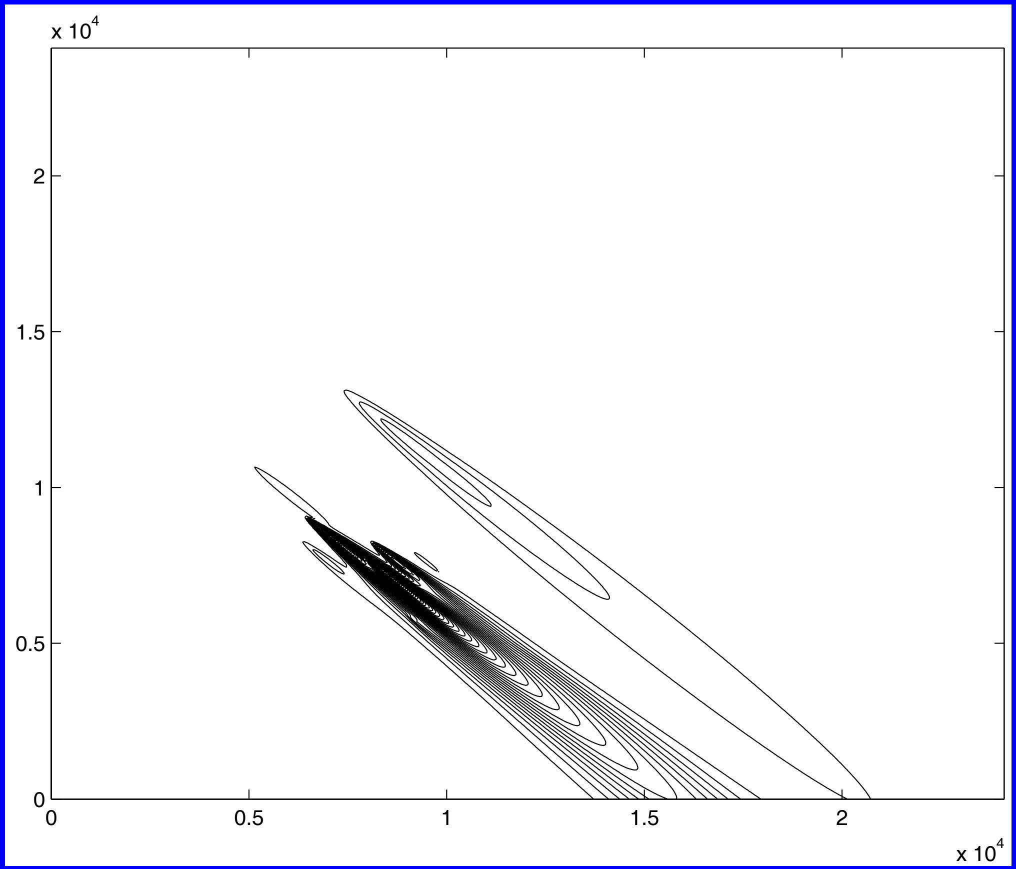
Numerical results - contour

The maximum pollution level of $l^* = 1.81068 \times 10^{-3} gm^{-3}$ in position $(x, y) = (8500, 7000)$.



Example - Air pollution abatement

Consider three plants ($\mathcal{P}_1$, $\mathcal{P}_2$ and $\mathcal{P}_3$), with emissions of e_1, e_2 and e_3, where $0 \leq e_i \leq 2$, $(i = 1, 2, 3)$ of a certain pollutant. By legal imposition the pollution level must not exceed a given threshold $(\mathcal{C}_0)$ under mean weather conditions, i.e., $\theta = 0$ and $\mathcal{U} = \left(\frac{1}{2\pi}\right)^2 ms^{-1}$. Consider $\mathcal{Q} = 1gs^{-1}$ and $\mathcal{C}_0 = \frac{1}{2}$. The remaining stacks data are

Source	a_i	b_i	h_i
1	0	1	1
2	0	0	1
3	2	-1	$\sqrt{2}$

Problem

The emission rate reduction is to be minimized.

$$\min_{r_1,r_2,r_3 \in R} 2r_1 + 4r_2 + r_3$$

$$s.t. \sum_{i=1}^{3} (2 - r_i)\mathcal{C}(x, y, 0, \mathcal{H}_i) \leq \mathcal{C}_0$$

$$0 \leq r_i \leq 2, \; i = 1, 2, 3$$

$$\forall (x, y) \in [-1, 4] \times [-1, 4].$$

Numerical results

Solution found $r^* = (0.987, 0.951, 0.943)$

The maximum pollution is attained at $(x, y)^1 = (1.100, 0.125)$, $(x, y)^2 = (1.100, 0.100)$ and $(x, y)^3 = (3.675, -0.625)$, where the sampling stations should be placed.
